Lab 2: Variables & Input

Python Lab · Section 1.1–1.2 (preview of 3.1)

Goal

Store data in variables and get input from the user to make a Mad Libs program.

Warm-up: Predict

```
a = 4
b = a
a = 10
print(a, b)
```

Predict the output. Why didn't b change?

AP Connection

- $x = 5$ in Python is $x \leftarrow 5$ in AP pseudocode.
- `input()` is like `INPUT()` — it gets a value from the user.
- Input and output (Topic 1.2).

Build It

Step 1. Create variables and print them. Use meaningful names!

```
name = "Jordan"
age = 16
print(name)
print(age)
```

Step 2. Get input from the user. `input()` always gives back a string.

```
name = input("What is your name? ")
print("Nice to meet you, " + name + "!")
```

Step 3. To do math with input, convert it with `int()`:

```
year = int(input("What year were you born? "))
print("You turn 18 in", year + 18)
```

Step 4. Build a Mad Libs: ask for at least 5 words (noun, verb, adjective, place, number) and print a funny story using them.

```
noun = input("Noun: ")
verb = input("Verb: ")
# ask for 3 more words...
print("Once upon a time, a " + noun + " decided to " + verb + "...")
```

Step 5. Test with a classmate (pair programming): the navigator suggests words while the driver types. Then switch roles.
